EC 1745 Midterm Notes Name: _____

EXCEL BASICS

- Every formula starts with **=**. Math: + − * / and ^ (power). Example: **=B2-B3**, **=B5*(1+B6)^2**.
- Point at cells instead of retyping numbers. **$** locks a cell when you copy a formula (**=B2/$B$20**); press F4 to add it.
- Rates as decimals: 5% = 0.05; 100 bp = 0.01. Dates: **=DATE(2025,10,7)**. Copy right/down: Ctrl+R / Ctrl+D.
- Type **=PV(** and Excel shows the inputs in order. Show as %: Home ▸ % button.

INCOME STATEMENT (top line → bottom line)

Labels in column A, one year per column (B = 2024, C = 2023). "type" = number given in the question.

#	Column A (label)	Column B
1	Year →	2024
2	**Revenue (sales)** ← TOP LINE	type
3	− Cost of goods sold (COGS)	type
4	**= Gross profit**	**=B2-B3**
5	− SG&A (operating costs)	type
6	**= EBITDA**	**=B4-B5**
7	− Depreciation & amortization	type
8	**= EBIT** (operating income)	**=B6-B7**
9	− Interest expense	type
10	**= Pretax income** (EBT)	**=B8-B9**
11	− Taxes (tax rate × EBT)	**=0.21*B10**
12	**= Net income** ← BOTTOM LINE	**=B10-B11**
13	− Dividends	type
14	**= Retained earnings** (kept)	**=B12-B13**

EPS = NI / shares. Retention ratio **b** = (NI − dividends) / NI.

BALANCE SHEET (snapshot on one date)

ASSETS	LIABILITIES & EQUITY
Cash	Accounts payable (AP)
+ Accounts receivable (AR)	+ Short-term debt
+ Inventory	**= Current liabilities**
= Current assets	+ Long-term debt
+ Gross PP&E	**= Total liabilities**
− Accum. depreciation	+ Shareholders' equity
= Net PP&E	
+ Other assets	
= TOTAL ASSETS	**= TOTAL LIAB. + EQUITY**

- **Total assets = total liabilities + equity**, always. One number missing (often cash)? Cash = total L+E − all other assets.
- Equity this year = equity last year + retained earnings + new stock − buybacks.
- Debt = short-term + long-term debt (AP is not debt). Only debt and equity given? Total assets = debt + equity.
- New cash balance: subtract AR, inventory and net PP&E from TL + equity.

CASH FLOW STATEMENT (cash ≠ net income)

Δ (delta) = change = this year − last year. Example: ΔAR = AR 2025 − AR 2024.

CFO = Net income + Depreciation − ΔNWC

ΔNWC = ΔAR + ΔI − ΔAP

− ↑AR − ↑Inventory + ↑AP (asset ↑ uses cash; liability ↑ gives cash)

= Cash from operations (CFO)

− CapEx, where **CapEx = ΔNet PP&E + depreciation**

= Cash from investing (CFI)

+ New debt (ΔDebt) + new stock − dividends

= Cash from financing (CFF)

CFO + CFI + CFF = change in cash on the balance sheet ✓

Free cash flow = EBIT × (1 − t) + Dep − CapEx − ΔNWC, where ΔNWC = ΔAR + ΔInv − ΔAP

RATIOS (use year-end numbers)

Gross margin	Gross profit / Revenue
Operating margin	EBIT / Revenue
Profit margin	Net income / Revenue
ROE	Net income / Equity
ROA	Net income / Total assets
Asset turnover	Revenue / Total assets
Equity multiplier	Total assets / Equity
DuPont	**ROE = Profit margin × Asset turnover × Equity multiplier**
Sustainable growth	ROE × b (or ROE·b / (1 − ROE·b)) b = retention ratio = retained earnings / net income, or 1 − dividend payout ratio
Internal growth	ROA × b (or ROA·b / (1 − ROA·b))
Current ratio	Current assets / Current liabilities
Interest coverage	EBIT / Interest expense
Debt-to-equity	Total debt / Equity

Profit margin = profitability; turnover = efficiency; multiplier = leverage (raises ROE and risk).

WHAT THE FIRM IS WORTH

Market cap = shares × share price (= market value of equity)

Enterprise value (EV) = market cap + debt (ST + LT) − excess cash

Given EV (e.g. EV = 8 × EBIT): equity value = EV − debt + cash

P/E = market cap / net income (= price / EPS). EV/EBITDA = EV / EBITDA

HOW TO ANSWER A RATIO QUESTION

1. Type the statements into Excel (templates above).
2. Put each ratio in its own labeled cell, as a formula pointing at the statement cells.
3. Format as % where it is a percent. Check that the DuPont product equals ROE.
4. Asked to interpret? Say which number rose or fell, and why it matters.

WORKED EXAMPLE (2025 exam, Ferrario)

Revenue 1,000 − COGS 600 = **GP 400** (gross margin 40%) − SG&A 100 = EBITDA 300 − Dep 60 = **EBIT 240** − interest 25 = EBT 215 − tax 21% (45.15) = **NI 169.85** − div 60 = RE 109.85.

Equity 1,200 + debt 500 = total assets 1,700. **ROE** = 169.85 / 1,200 = 14.15% = 16.99% × 0.588 × 1.417. b = 109.85 / 169.85 = 0.647; SGR = 14.15% × 0.647 = 9.15%.

EV = 8 × 240 = 1,920. Equity = 1,920 − 500 = 1,420. P/E = 1,420 / 169.85 = 8.36.

TIME VALUE OF MONEY (draw a timeline; t = 0 is today)

PV = CF / (1+r)^t FV = PV × (1+r)^t. Compare offers at the **same date**; bigger PV wins.

Annuity (same C at t = 1…N): PV = C/r × (1 − 1/(1+r)^N)

Growing annuity: PV = $C_1/(r - g) \times (1 - ((1+g)/(1+r))^N)$

Perpetuity C/r. Growing perpetuity $C_1/(r - g)$. First payment today (annuity due): multiply PV by (1+r).

By hand ("dumb"): row 1 = years 0…N; row 2 = cash flows; row 3 = **=1/(1+$B$1)^C5** (discount factor); row 4 = CF × factor; PV = **=SUM(row 4)**. Value at year T = PV × (1+r)^T.

=PV(r,n,-C)	Today's value of n payments of C
=FV(r,n,-C)	Value at year n
=PMT(r,n,-PV)	Payment that pays off PV
=RATE(n,C,-PV)	Discount rate implied by the deal
=NPER(r,C,-PV)	Number of payments
=NPV(r,C1:Cn)	Starts at t = 1! Add CF0 yourself
=IRR(C0:Cn)	Rate where NPV = 0 (C0 negative)

Minus signs: Excel needs money paid and money received to have opposite signs. Payments start today? Add **,0,1** at the end: **=PV(r,n,-C,0,1)**.

INTEREST RATES & LOANS

APR = quoted annual rate. Per-period rate = APR / periods per year.

EAR = (1 + APR/k)^k − 1 = **=EFFECT(APR,k)**. Bond EAY = (1 + y/2)^2 − 1.

Monthly loan payment: **=PMT(APR/12,years*12,-loan)**. Balance after k payments: **=PV(APR/12,N-k,-payment)**.

Restructuring: the new deal must have the same PV at the same rate. Solve for the unknown with PMT / RATE / NPER.

BOND WORDS

Par (face) = 100, repaid at maturity. **Coupon rate** = % of par paid per year, in 2 halves (5% → 2.50 every 6 months).

Yield (YTM) = discount rate that makes PV of the bond's cash = price. Quoted as APR; use y/2 per half-year.

Yield ↑ ⇒ price ↓. Coupon > yield ⇒ price > 100. Issued at par ⇒ coupon = yield.

Corporate yield = Treasury yield + spread. 1 bp = 0.01% = 0.0001.

Basis: 0 = 30/360 (corporates), 1 = actual/actual (Treasuries). Settlement = date you buy.

BONDS WITHOUT DATES ("dumb")

Price	**=PV(yield/2,2*years,-coupon*100/2,-100)**
YTM	**=2*RATE(2*years,coupon*100/2,-price,100)**
EAY	**=(1+yield/2)^2-1**
Coupon rate	**=2*PMT(yield/2,2*years,-price,100)/100**

Price needs the yield. YTM needs the price (per 100, e.g. 87.91). EAY needs only the YTM. years = years LEFT.

Bond exchange: the new bond must be worth what the old one is worth. Solve for the new coupon with PMT. Face needed to raise $X = X / (price/100).

Market value of all bonds = face outstanding × price / 100. Example: 400 × 87.91 / 100 = 351.62.

BONDS WITH DATES ("smart"), STEP BY STEP

1. Type inputs: settle **=DATE(…)**, maturity **=DATE(…)**, coupon, price or yield, 2, basis.
2. Treasury yield: **=YIELD(settle,mat,coupon,price,100,2,1)**
3. Corporate yield = Treasury yield + spread.
4. Clean price: **=PRICE(settle,mat,coupon,yield,100,2,0)**
5. Days since last coupon **=COUPDAYBS(settle,mat,2,0)**; days in period **=COUPDAYS(settle,mat,2,0)** (180 on 30/360).
6. **Accrued interest** = coupon×100/2 × COUPDAYBS / COUPDAYS
7. **Dirty price = clean + accrued.** Dealer QUOTES clean; you PAY dirty.
8. **=DURATION(settle,mat,coupon,yield,2,basis)** and **=MDURATION(…same…)**
9. % price change ≈ −MDURATION × Δyield (+100 bp = +0.01).
10. Actual: PRICE at the new yield + same accrued, vs. old dirty price.

Also: **COUPPCD** / **COUPNCD** = previous/next coupon date (format as date); **COUPNUM** = coupons left.

DURATION (what, why, how)

What: the average time (in years) until you get the bond's cash, weighted by PV.

Why: it tells how much the price moves when yields move (interest-rate risk). Higher duration = more risk. Used to compare bonds and to match assets to liabilities.

Macaulay D = Σ (t × PV of CF) / price. Modified MD = D / (1 + y/2)

% price change ≈ −MD × Δy. MD = 7.7 and yields +1% ⇒ price ≈ −7.7%.

From two prices: D ≈ −(% change in price) / (change in yield).

By hand, one row per coupon k = 1…N (row 2 shown):

A: k B: years **=A2/2** C: cash **=c*100/2** (+100 in last row)

D: PV **=C2/(1+y/2)^A2** E: **=B2*D2**

Price = SUM(D). **D = SUM(E) / SUM(D).** Between coupon dates, periods = k − 1 + COUPDAYSNC/COUPDAYS.

No dates given?

=DURATION(DATE(2000,1,1),DATE(2000+years,1,1),c,y,2)

Zero-coupon D = maturity. Longer maturity ⇒ higher D. Higher coupon ⇒ lower D.

Convexity: the real price change beats the estimate (falls less, rises more).

WORKED EXAMPLES (check your syntax)

Contracts, r = 10%: 30/yr × 10 yrs: **=PV(0.1,10,-30)** = 184.34. 35/yr × 8 yrs: **=PV(0.1,8,-35)** = 186.72, so pick #2. Value at year 10: **=FV(0.1,10,-30)** = 478.12; **=FV(0.1,8,-35)*1.1^2** = 484.31.

Ma Corp bond:

=PRICE(DATE(2024,10,17),DATE(2054,5,15),0.1,0.12,100,2,0) = 83.845 clean. COUPDAYBS = 152, COUPDAYS = 180, accrued = 5 × 152/180 = 4.222, dirty = 88.067. MDURATION = 7.804; +25 bp ⇒ ≈ −7.804 × 0.0025 = −1.95%.
